Welcome and Introductions

- I
 - ▶ ...am an Assistant Professor in Sociology.
 - ▶ ...am trained in political science and statistics
 - ▶ ...do research in statistical text analysis and causal inference
 - ▶ ...love doing collaborative research
 - ▶ ...talk very quickly
- Your Preceptors
 - ▶ Maxwell Fineman
 - ▶ Angela Li

Overview

- Goal: train you in statistical thinking.
- Fundamentally a graduate course for sociologists, but also useful for research in other fields, policy evaluation, industry etc.
- Difficult course but with many resources to support you.
- When we are done you will be able to teach **yourself** many things
- Syllabus is a useful resource including philosophy of the class.

Specific Goals

- critically **read** and **reason** about quantitative social science using linear regression techniques.
- **conduct**, **interpret**, and **communicate** results from analysis using multiple regression.
- explain the limitations of observational data for making **causal** claims and distinguish between identification and estimation.
- understand the logic and assumptions of several modern **designs** for making causal claims.
- write **clean, reusable, and reliable** R code in tidyverse style.
- feel **empowered** working with data

Why R?

- It will give you **super powers** (but not at first)
- It is free and **open source**
- It is the *de facto* **standard** in many applied statistical fields

Artwork by @allison_horst

Why RMarkdown?

 - Ways to Learn
 - Final Details
- 2 Core Ideas
 - What is Statistics?
- 3 Introduction to Probability
 - What is Probability?
 - Sample Spaces and Events
 - Probability Functions
- 4 Three Big Ideas in Probability
 - Marginal, Joint and Conditional Probability
 - Bayes' Rule
 - Independence
- 5 Fun With Audits and Magic Tricks!

Mathematical Prerequisites

- No formal pre-requisites.
- Balance of rigor and intuition.
 - ▶ no rigor for rigor's sake.
 - ▶ we will tell you *why* you need the math, but also feel free to ask.
 - ▶ course focus on how to **reason** about statistics, **not just memorize** guidelines.
- The key to success is pushing on what you **don't know** even when doing so is uncomfortable.
- This class is **not** about innate statistical aptitude, it is about **effort**.
- We all come from very different backgrounds. Please have **patience** with **yourself** and with **others**.

Ways to Learn

- **Lectures**
learn broad topics
- **Precept**
learn data analysis skills, get targeted help on assignments
- **Problem Sets**
reinforce understanding of material, practice
- **Ed**
ask questions of us and your classmates
- **Office Hours**
ask us even more questions, but (sort of) in-person

Problem Sets

- Schedule (due Wednesday at 8PM eastern)
- Grading and solutions
- Collaboration policy
- You may find these difficult. Start early and seek help!
- Initial sense of disconnect (coding & math)

Problem sets are the most important part of the class!

Ways to Learn

- Lectures and Precept
- Daily Feedback
- Readings and Slides
- Ed
- Office Hours
- Problem Sets
- Instructor Office Hours
- Final Exam Prep
- External Consulting

Your Job: work hard and **get help** when you need it!

Staying in Touch

Can we go
over Bayes'
Rule again?

A Note on Reading

- Think of the lecture slides as primary reading.
- If you want material to read, come talk to me about recommendations.
- Suggested Books (more in the syllabus!):
 - ▶ Angrist and Pischke. 2008. *Mostly Harmless Econometrics*
 - ▶ Aronow and Miller. 2019. *Foundations of Agnostic Statistics*
 - ▶ Blitzstein and Hwang. 2019. *Introduction to Probability: Second Edition*
- A somewhat obvious tip: don't skip the math!

Advice from Prior Generations

- Ask questions if you don't know what's going on!
- Investing a considerable amount of time in getting familiar with R and its various tools will pay off in the long run!
- Go over the lecture slides each week. This can be hard when you feel like you're treading water and just staying afloat, but I wish I had done this regularly.
- It's challenging but very doable and rewarding if you put the time in. There are plenty of resources to take advantage of for help.
- I found it helpful to read through the lecture slides again after I had opened the problem set. It made it easier to create connections between what we went through and how to do it.
- Go over your psets and the pset solutions the moment they are graded as a habit and figure out what you don't know.

Outline of Topics

Outline in reverse order:

- **Causal Inference:**
inferring counterfactual effect given association.
- **Regression:**
estimate association.
- **Inference:**
estimating things we don't know from data.
- **Probability:**
learning what data we would expect if we did know the truth.

Probability $\rightarrow$ Inference $\rightarrow$ Regression $\rightarrow$ Causal Inference

Attribution and Thanks

- My philosophy on teaching: don't reinvent the wheel
customize, refine, improve.
- Huge thanks to those who have provided slides particularly:
Matt Blackwell, Adam Glynn, Justin Grimmer, Jens Hainmueller,
Erin Hartman, Kevin Quinn
- Also thanks to those who have discussed with me at length
including Dalton Conley, Chad Hazlett, Gary King, Kosuke Imai,
Matt Salganik and Teppei Yamamoto.
- Previous generations of preceptors who have made important
contributions to the course: Clark Bernier, Emily Cantrell, Elisha
Cohen, Ian Lundberg, Simone Zhang, Alex Kindel, Ziyao Tian,
Shay O'Brien, Emily Cantrell, Alejandro Schugurensky.
- Shay O'Brien for many hand-drawn illustrations.

Welcome To Class!

Be sure to read the syllabus for more details.

1 Course Structure

- Bayes' Rule
- Independence

5 Fun With Audits and Magic Tricks!

What is Statistics?

- Branch of mathematics studying collection and analysis of **data**
- The name statistic comes from the word **state**
- The arc of developments in statistics
 - 1) an **applied** scholar has a **problem**
 - 2) they **solve** the problem by inventing a **specific** method
 - 3) statisticians **generalize** and **export** the best of these methods
- Relatively recent field (started at end of 19th century)
- Goal: principled guesses with known properties based on stated assumptions.
- In practice, an essential part of research, policy making, political campaigns, selling people things. . .

Why study probability?

It enables **inference**.

In Picture Form

In Picture Form

Example: The Lady Tasting Tea

- **The Story Setup**
(lady discerning about tea)
- **The Experiment**
(perform a taste test)
- **The Hypothetical**
(count possibilities)
- **The Result**
(boom she was right)

Tea-Tasting Distribution		
Success count	Permutations of selection	Number of permutations
0	0000	$1 \times 1 = 1$
1	000X, 00X0, 0X00, X000	$4 \times 4 = 16$
2	00XX, 0X0X, 0XX0, X0X0, XX00, X00X	$6 \times 6 = 36$
3	00XX, X00X, XX0X, XXX0	$4 \times 4 = 16$
4	XXXX	$1 \times 1 = 1$
Total		70

This became the Fisher Exact Test.

A Note on Fisher and the History of Statistics

- The statistician in that story was Sir Ronald Fisher, arguably the most influential statistician of the 20th century.
- Besides founding key areas of statistics, Fisher was also one of the founders of population genetics.
- He was also a eugenicist and a racist.
- Statistics has been used intermittently as a force for progress and a force against progress.

- 5 Fun With Audits and Magic Tricks!

From 'Probably' to Probability

Why Probability?

- Helps us envision **hypotheticals**
- Describes uncertainty in how the data is generated
- Estimates probability that something will happen
- Thus: we need to know how **probability** gives rise to **data**

Intuitive Definition of Probability

While there are several **interpretations** of what probability is, most modern (post 1935 or so) researchers agree on an **axiomatic definition** of probability.

3 Axioms (Intuitive Version):

- 1 The probability of any particular event must be **non-negative**.
- 2 The probability of **anything** occurring among all possible events must be **1**.
- 3 The probability of **one of many mutually exclusive events** happening is the **sum of the individual** probabilities.

All the rules of probability can be derived from these axioms. To state them formally, we first need some definitions.

Sample Spaces

To define **probability** we need to define the set of **possible outcomes**.

The sample space is the set of all possible outcomes, and is often written as Ω .

For example, if we flip a coin twice, there are four possible outcomes,

$$\Omega = \{ \{heads, heads\}, \{heads, tails\}, \{tails, heads\}, \{tails, tails\} \}$$

Thus the table in Lady Tasting Tea was defining the **sample space**.
(Note we defined illogical guesses to be $\text{prob} = 0$)

A Running Visual Metaphor

Imagine that we sample one apple from a bag.
Looking in the bag we see:

The sample space is:

$$\Omega = \{ \text{apple}, \text{apple}, \text{apple}, \text{apple} \}$$

Events

Events are subsets of the sample space.

For example, if

$$\Omega = \{\text{apple}, \text{apple}, \text{apple}, \text{apple}\}$$

then

$$\{\text{apple}, \text{apple}, \text{apple}\}$$

and

$$\{\text{apple}\}$$

are both **events**.

Events Are a Kind of Set

Sets are **collections** of things, in this case collections of **outcomes**

One way to define an event is to describe the **common property** that all of the outcomes share. We write this as

$$\{\omega | \omega \text{ satisfies Property they share}\},$$

Example:

If $A = \{\omega | \omega \text{ has a leaf}\}$:

 $\in A$,  $\in A$,  $\notin A$,  $\notin A$

Complement

A **complement** of event A , denoted A^c , is also a set.

A^c , is everything else not in A .

and

are **complements**.

$$A^c = \{\omega \in \Omega \mid \omega \notin A\}.$$

Important complement: $\Omega^c = \emptyset$, where $\emptyset$ is the **empty set**.

Unions and Intersections

The **union** of two events, A and B is the event that A or B occurs:

$$\begin{aligned} \text{🌿} \cup \text{🍏} &= \\ \{\text{🍏}, \text{🍏}, \text{🍏}\} & \quad A \cup B = \{\omega \mid \omega \in A \text{ or } \omega \in B\}. \end{aligned}$$

The **intersection** of two events, A and B is the event that both A and B occur:

$$\begin{aligned} \text{🌿} \cap \text{🍏} &= \\ \{\text{🍏}\} & \quad A \cap B = \{\omega \mid \omega \in A \text{ and } \omega \in B\}. \end{aligned}$$

Operations on Events

We say that two events A and B are **disjoint** or **mutually exclusive** if they don't share any elements or that $A \cap B = \emptyset$.

An event and its complement A and A^c are by definition disjoint.

$$A \cap B = \emptyset$$

Sample spaces can have infinite events where we will often write the different events using subscripts of the same letter: $A_1, A_2, \dots, A_\infty$ (e.g. imagine an event that was the count of some object)

Probability Function

A **probability function** $P(\cdot)$ is a function defined over all subsets of a sample space Ω that satisfies the following three axioms:

1) $P(A) \geq 0$ for all A in the set of all events. **nonnegativity**

1. ~~$P(\text{apple}) = -.5$~~

2) $P(\Omega) = 1$ **normalization**

2. $P(\{\text{apple}, \text{apple}, \text{apple}, \text{apple}\}) = 1$

3) if events $A_1, A_2, \dots$ are mutually exclusive then
 $P(\bigcup_{i=1}^{\infty} A_i) = \sum_{i=1}^{\infty} P(A_i)$.
additivity

3. $P(\text{apple} \cup \text{apple}) = P(\text{apple}) + P(\text{apple})$
when apple and apple are mutually exclusive.

All the rules of probability can be derived from these axioms.
(See Blitzstein & Hwang, Def 1.6.1.)

Three Big Ideas

Marginal, joint, and conditional probabilities

Bayes' rule

Independence

Marginal and Joint Probability

So far we have only considered situations where we are interested in the probability of a single event A occurring. We've denoted this $P(A)$. $P(A)$ is sometimes called a **marginal probability**.

Suppose we are now in a situation where we would like to express the probability that an event A and an event B occur. This quantity is written as $P(A \cap B)$, $P(B \cap A)$, $P(A, B)$, or $P(B, A)$ and is the **joint probability** of A and B .

$$P(\text{🍌}, \text{🍏}) = P(\text{🍏}) = P(\text{🍌} \cap \text{🍏})$$

$$P(\text{🍏}) = 7/10$$

$$P(\text{🍏}, \text{🍏}) = 4/10$$

Conditional Probability

The “soul of statistics”

If $P(A) > 0$ then the probability of B conditional on A is

$$P(B|A) = \frac{P(A, B)}{P(A)}$$

This implies that

$$P(A, B) = P(A)P(B|A) = P(B)P(A|B)$$

Hopefully this second formulation is intuitive!

Conditional Probability: A Visual Example

$$P(\text{brown stem, green leaf} | \text{apple with bite}) = \frac{P(\text{brown stem, green leaf, apple with bite})}{P(\text{apple with bite})}$$

Conditional Probability: A Visual Example

$$P(\text{🍏} | \text{🍏}) = \frac{P(\text{🍏}, \text{🍏})}{P(\text{🍏})}$$

Conditional Probability: A Visual Example

$$P(\text{leafy} | \text{bitten}) = \frac{P(\text{leafy}, \text{bitten})}{P(\text{bitten})}$$

Law of Total Probability (LTP)

With 2 Events:

$$\begin{aligned}P(B) &= P(B, A) + P(B, A^c) \\ &= P(B|A)P(A) + P(B|A^c)P(A^c)\end{aligned}$$

$$\begin{aligned}P(\text{🍏}) &= P(\text{🍏}) + P(\text{🍏}) \\ &= P(\text{🍏} | \text{🌿}) \times P(\text{🌿}) + P(\text{🍏} | \text{🍷}) \times P(\text{🍷})\end{aligned}$$

In general, if $\{A_i : i = 1, 2, 3, \dots\}$ forms a partition of the sample space, then

$$\begin{aligned}P(B) &= \sum_i P(B, A_i) \\ &= \sum_i P(B|A_i)P(A_i)\end{aligned}$$

Example: Voter Mobilization

Suppose that we have put together a voter mobilization campaign and we want to know what the **probability of voting** is after the campaign: $P(\text{vote})$. We know the following:

- $P(\text{vote}|\text{mobilized}) = 0.75$
- $P(\text{vote}|\text{not mobilized}) = 0.15$
- $P(\text{mobilized}) = 0.6$ and so $P(\text{not mobilized}) = 0.4$

Note that mobilization **partitions** the data. Everyone is either mobilized or not. Thus, we can apply the LTP:

$$\begin{aligned}P(\text{vote}) &= P(\text{vote}|\text{mobilized})P(\text{mobilized}) + \\&\quad P(\text{vote}|\text{not mobilized})P(\text{not mobilized}) \\&= 0.75 \times 0.6 + 0.15 \times 0.4 \\&= .51\end{aligned}$$

Engaged and Disengaged Respondents

PNAS

RESEARCH ARTICLE

POLITICAL SCIENCE

OPEN ACCESS

Current research overstates American support for political violence

Kevin M. Doonan¹*, John C. Coons², Matthew J. Green³, and Clayton Kopp⁴

Edited by Jeremy Epstein, University of Chicago, Chicago, IL, received September 1, 2020; accepted January 4, 2021; by Editorial Board Member Elizabeth Loft

Political scientists, pundits, and citizens worry that America is entering a new period of violent partisan conflict. Proximate survey data show that a large share of Americans (between 83% and 40%) support politically motivated violence. Yet, despite media attention, political violence is rare, amounting to a little more than 1% of violent hate crimes in the United States. We reconcile these seemingly conflicting facts with four large survey experiments ($n = 4,904$), demonstrating that self-reported attitudes on political violence are biased upward because of respondent disengagement and survey questions that allow multiple interpretations of political violence. Addressing question wording and respondent disengagement, we find that the median of existing estimates of support for partisan violence is nearly 6 times larger than the median of our estimates (18.4% versus 2.9%). Critically, we show the prior estimates overstate support for political violence because of random responding by disengaged respondents. Respondent disengagement also inflates the relationship between support for violence and previously identified correlates by a factor of 4. Partial identification bounds imply that, under generous assumptions, support for violence among engaged and disengaged respondents is at most 6.86%. Finally, nearly all respondents support criminally charging suspects who commit acts of political violence. These findings suggest that, although recent acts of political violence dominate the news, they do not portend a new era of violent conflict.

political violence | affective polarization | democratic norms

Proximate recent works (1–3)—cited in PNAS (4, 5), *The American Journal of Political Science* (6), 60 online videos and books, and 40 news articles that, together, have generated over 2,281,183 Twitter engagements—asserts that large segments of the American population now support politically motivated violence. These studies report that up to 44% of Americans would endorse intentional violence in some undetermined future event (1–3, 7). This survey work fits within a media landscape that regularly mixes the specter of political violence. Since 2016, we counted 2,863 mentions of political violence on news television, more than 630 news stories about political violence, and over 2.0 million tweets on the topic of the January 6 riot alone (see *SI Appendix, section 1* for details for all items in this paragraph). Political violence, however, remains exceedingly rare in the United States, amounting to 48 incidents (8) in 2019 (the most recent year for which data are available) compared to 1,526 incidents of nonpolitical violent hate crimes (9) and 1,203,808 total violent crimes (10) documented by the Department of Justice.

Significance

Different political events show that members of extreme political groups support partisan violence, and survey evidence superficially shows widespread public support. We show, however, that, after accounting for survey-based measurement error, support for partisan violence is far more limited. Prior estimates overstate support for political violence because of random responding by disengaged respondents and because of a reliance on hypothetical questions about violence in general instead of questions on specific acts of political violence. These same issues also cause the magnitude of the relationship between previously identified correlates and partisan violence to be overstated. As policy makers consider interventions designed to dampen support for violence, our results provide critical information about the magnitude of the problem.

Three Big Ideas

Marginal, joint, and conditional probabilities

Bayes' rule

Independence

Bayes' Rule

- Often we have information about $P(B|A)$, but want $P(A|B)$.
- When this happens, always think: Bayes' rule
- Bayes' rule: if $P(B) > 0$, then:

$$P(A|B) = \frac{P(B|A)P(A)}{P(B)}$$

Bayes' Rule Mechanics

$$P(\text{🍏} | \text{🍏}) = \frac{P(\text{🍏} | \text{🍏}) P(\text{🍏})}{P(\text{🍏})}$$

Bayes' Rule Mechanics

$$P(\text{brown leaf} | \text{red apple}) = \frac{P(\text{red apple} | \text{brown leaf}) P(\text{brown leaf})}{P(\text{red apple})}$$

Bayes' Rule Mechanics

$$P(\text{brown leaf} | \text{red apple}) = \frac{P(\text{red apple} | \text{brown leaf}) P(\text{brown leaf})}{P(\text{red apple})}$$

Bayes' Rule Mechanics

$$P(\text{brown leaf} | \text{red apple}) = \frac{P(\text{red apple} | \text{brown leaf}) P(\text{brown leaf})}{P(\text{red apple})}$$

Example: Race and Names

What the Demolition of Public Housing Teaches Us about the Impact of Racial Threat on Political Behavior

Ryan D. Enos Harvard University

How does the context in which a person lives affect his or her political behavior? I exploit an event in which demographic context was exogenously changed, leading to a significant change in voters' behavior and demonstrating that voters react strongly to changes in an outgroup population. Between 2000 and 2004, the reconstruction of public housing in Chicago caused the displacement of over 25,000 African Americans, many of whom had previously lived in close proximity to white voters. After the removal of their African American neighbors, the white voters' turnout dropped by over 10 percentage points. Consistent with psychological theories of racial threat, their change in behavior was a function of the size and proximity of the outgroup population. Proximity was also related to increased voting for conservative candidates. These findings strongly suggest that racial threat occurs because of attitude change rather than selection.

Example: Race and Names

- Note that the Census collects information on the distribution of names by race.
- For example, Washington is the most common last name among African-Americans in America:
 - ▶ $P(\text{AfAm}) = 0.132$
 - ▶ $P(\text{not AfAm}) = 1 - P(\text{AfAm}) = .868$
 - ▶ $P(\text{Washington}|\text{AfAm}) = 0.00378$
 - ▶ $P(\text{Washington}|\text{not AfAm}) = 0.000061$
- We can now use Bayes' Rule

$$P(\text{AfAm}|\text{Wash}) = \frac{P(\text{Wash}|\text{AfAm})P(\text{AfAm})}{P(\text{Wash})}$$

Example: Race and Names

Note we don't have the probability of the name Washington.

Remember that we can calculate it from the LTP since the sets African-American and not African-American partition the sample space:

$$\begin{aligned} P(\text{AfAm}|\text{Wash}) &= \frac{P(\text{Wash}|\text{AfAm})P(\text{AfAm})}{P(\text{Wash})} \\ &= \frac{P(\text{Wash}|\text{AfAm})P(\text{AfAm})}{P(\text{Wash}|\text{AfAm})P(\text{AfAm}) + P(\text{Wash}|\text{not AfAm})P(\text{not AfAm})} \\ &= \frac{0.132 \times 0.00378}{0.132 \times 0.00378 + .868 \times 0.000061} \\ &\approx 0.9 \end{aligned}$$

Three Big Ideas

Marginal, joint, and conditional probabilities

Bayes' rule

Independence

Independence

Intuitive Definition

Events A and B are independent if knowing whether A occurred provides no information about whether B occurred.

i.e. a formalization of what it means for two events to be unrelated.

Formal Definition

$$P(A, B) = P(A)P(B) \implies A \perp\!\!\!\perp B$$

With all the usual > 0 restrictions, this implies

- $P(A|B) = P(A)$
- $P(B|A) = P(B)$

Conditional Independence

$$P(A, B|C) = P(A|C)P(B|C) \implies A \perp\!\!\!\perp B|C$$

Independence is a massively important concept in statistics.

Independence, the Heroic Assumption

Deploy with Caution!

But Really, Why Probability?

- Envision **hypothetical** data given some assumed by intrinsically uncertain system.
- Set us up to do **inference** (i.e. run that backwards!).
- A **mathematical model** that hopefully corresponds well to real behavior → sometimes this correspondence is direct and other times it is more like a loose analogy.
- It can feel **frustrating** to start with probability if you came to class wanting to **analyze data**, but it is the single most important piece of infrastructure.
