Where We've Been and Where We're Going...

- Last Week

- ▶ welcome and outline of course
- ▶ described uncertain outcomes with **probability**.

- This Week

- ▶ define **random variables**
- ▶ summarize random variables using **expectation** and **variance**
- ▶ properties of **joint** and **conditional** distributions
- ▶ famous distributions

- Next Week

- ▶ **estimating** these features from data
- ▶ estimating **uncertainty**

- Long Run

- ▶ probability $\rightarrow$ inference $\rightarrow$ regression $\rightarrow$ causal inference

- 1 Definition of Random Variables
 - What is a Random Variable?
- 2 Discrete Distributions
- 3 Continuous Distribution
- 4 Expectation as a Measure of Central Tendency
- 5 Variance as a Measure of Dispersion
- 6 Fun With Averages
- 7 Joint and Conditional Distributions
- 8 Characterizing Conditional Distributions

Example: Ballot Order

Evidence suggests that candidates gain a small advantage from ballot order.

As a response, in 2008 New Hampshire chose a letter from the alphabet and then listed the candidates in alphabetical order **starting with that letter**.

We can use probability to assess the “fairness” of this process.

We will do this by introducing a random variable X to be Barack Obama's position on the 2008 New Hampshire primary ballot.

What is a Random Variable?

Intuition: **functions** that map outcomes to numbers.

Formal: X is a function that maps the **sample space** to the **real numbers**.

Imagine two coin flips

$$\Omega = \{\{heads, heads\}, \{heads, tails\}, \{tails, heads\}, \{tails, tails\}\}$$

we could define a random variable $X(\omega)$ to be the function that returns the number of heads for each element (ω) of the sample space (Ω).

- $X(\{heads, heads\}) = 2$
- $X(\{heads, tails\}) = 1$
- $X(\{tails, heads\}) = 1$
- $X(\{tails, tails\}) = 0$

We will generally suppress the function notation and just refer to X .

A Visual Example

A Visual Example

A Visual Example

A Brief Note on Notation

- We almost always use capital roman letters for the “name” of the random variable such as X .
- We refer to a **fixed** value with a lower case letter x .
- So we might write $P(X = x)$ to be the probability that the number of heads we observe is equal to some fixed value x .
- We will sometimes write out the mapping from the sample space to the random variable. For example,

$$X = \begin{cases} 1 & \text{if heads} \\ 0 & \text{if tails} \end{cases}$$

- Other times the sample space is already numeric so its more obvious (e.g. how many minutes until the train arrives).

Quick FAQ

- Why have random variables at all?
it makes the math easier, even across very different sample spaces.
- Why are they random variables?
they are realizations of a stochastic process (i.e. randomness in the outcome, not the mapping).
- Is it really easier this way? It seems hard.
random variables are about bridging the abstract math and the concrete world. that can be hard, but it is super important and better than the alternative!

NH Ballot Order Example

Candidates:

- Joe Biden
- Hillary Clinton
- Chris Dodd
- John Edwards
- Mike Gravel
- Dennis Kucinich
- Barack Obama
- Bill Richardson

$$X = \left\{ \begin{array}{l} 1 \\ 2 \\ 3 \\ 4 \\ 5 \\ 6 \\ 7 \\ 8 \end{array} \right.$$

A,B,C,D,E,F,G,H,I,J,K,L,M,N,O,P,Q,R,S,T,U,V,W,X,Y,Z

X is a random variable indicating Obama's position on the ballot. Highlighted letters are those leading to a given ballot position. Highlighted individual is first.

Discrete Distributions

- The **distribution** of a random variable specifies the probability of all events associated with that random variable.
- For discrete distributions, the random variable X takes on a **finite**, or a **countably infinite** number of values.
- A common shorthand is to think of discrete random variables taking on distinct values.
- A **probability mass function** (PMF) and a **cumulative distribution function** (CDF) are two common ways to define the probability distribution for a discrete random variable.
- Probability mass functions provide a compact way to represent information about **how likely** various outcomes are.

Where do Distributions Come From?

The probabilities associated with each realization of the random variables come from the underlying stochastic realization of the sample space.

Example: New Hampshire

Candidates:

- Joe Biden
- Hillary Clinton
- Chris Dodd
- John Edwards
- Mike Gravel
- Dennis Kucinich
- Barack Obama
- Bill Richardson

$$p_X(x) = \left\{ \begin{array}{ll} 4/26 & x = 1 \\ 4/26 & x = 2 \\ 2/26 & x = 3 \\ 1/26 & x = 4 \\ 1/26 & x = 5 \\ 1/26 & x = 6 \\ 10/26 & x = 7 \\ 3/26 & x = 8 \end{array} \right.$$

A,B,C,D,E,F,G,H,I,J,K,L,M,N,O,P,Q,R,S,T,U,V,W,X,Y,Z

Probability of the random variable equaling a number is just the probability of the underlying event (subset of the sample space).

Discrete Probability Mass Functions

Definition (Probability Mass Function)

The **probability mass function** (PMF) of a **discrete** random variable X is the function p_X given by,

$$p_X(x) = P(X = x)$$

Understanding the Notation:

- $X = x$ is defining an event.

More formally we might say, $\{X = x\}$ is shorthand for $\{\omega \in \Omega : X(\omega) = x\}$ which can be read as the set of realizations ω in the sample space Ω such that the function $X(\omega)$ returns the fixed value x .

- Later we will drop the subscript when it is clear from context.

Three key properties:

- this will always be **non-negative**.
- the **support** of X is the set of values where the PMF is non-zero.
- $\sum_x p_X(x) = 1$.

NH Obama Ballot Position PMF Plot

NH Obama Ballot Position PMF Plot

Cumulative Distribution Function

Definition (Cumulative Distribution Function)

The **cumulative distribution function** (CDF) of a random variable X is the function F_X given by,

$$F_X(x) = P(X \leq x)$$

Key properties:

- **non-decreasing**
- **right-continuous**
- converges to 0 and 1 in the limits

NH Obama Ballot Position CDF Plot

NH Obama Ballot Position CDF Plot

Example Discrete Distributions

- A major advantage of random variables is that they often have a distribution with a known form (that comes with known results!)
 - ▶ **Bernoulli distribution:** Let X be a binary variable with $P(X = 1) = \pi$ and, thus, $P(X = 0) = 1 - \pi$, where $\pi \in [0, 1]$. It has PMF:

$$p_X(x) = \pi^x(1 - \pi)^{1-x} \quad \text{for } x \in \{0, 1\}.$$

- ▶ **Discrete Uniform distribution:** Let X be a random variable that puts equal probability on each value that X can take:

$$p_X(x) = \begin{cases} 1/k & \text{for } x = 1, \dots, k \\ 0 & \text{otherwise} \end{cases}$$

- We can summarize these distributions with one number

- 1 Definition of Random Variables
- 2 Discrete Distributions
- 3 Continuous Distribution
 - Defining a Continuous Random Variable
 - Probability Density Functions and Cumulative Distribution Functions
 - Subtleties of the Continuous Setting
- 4 Expectation as a Measure of Central Tendency
- 5 Variance as a Measure of Dispersion
- 6 Fun With Averages
- 7 Joint and Conditional Distributions

Continuous Distributions

- Continuous random variables take on an **uncountably infinite** number of values.
- This is often a useful approximation when variables take many values.
- A **probability density function** (PDF) and a **cumulative distribution function** (CDF) are two common ways to define the distribution for a continuous random variable.
- They are similar to the discrete case with a few subtle differences.

Calculus Review: Integration

Suppose we have some function $f(x)$

What is the area under $f(x)$ between $\frac{1}{2}$ and 1?

$$\text{Area under curve} = \int_{1/2}^1 f(x) dx = F(1) - F(1/2)$$

Continuous Random Variable

A continuous random variable has a **continuous** cumulative distribution function (CDF) which, as in the discrete case, defines the probability that $P(X \leq x)$.

Definition (Continuous Distribution)

A random variable has a **continuous distribution** if its CDF is differentiable. We also allow there to be endpoints (or finitely many points) where the CDF is continuous but not differentiable, as long as the CDF is differentiable everywhere else. (Blizstein and Hwang Definition 5.1.1)

Probability Density Function (PDF)

The **probability density function** is the analog of the probability mass function for discrete random variables.

Definition (Probability density function)

For a continuous random variable X with CDF F_X , the **probability density function** of X is the derivative f of the CDF, given by $f_X(x) = \frac{d}{dx} F_X(x)$

Key Properties:

- **non-negative**
- integrates to 1. $\int_{-\infty}^{\infty} f_X(x) dx = 1$
- for any measurable set of real numbers B ,

$$P(X \in B) = \int_B f_X(x) dx$$

Defining the CDF in terms of the PDF

Definition (CDF of a Continuous Random Variable)

For a continuous random variable X define its cumulative distribution function $F_X(x)$ as,

$$F_X(t) = P(X \leq t) = \int_{-\infty}^t f_X(x) dx$$

A Visual Example

Imagine you choose a number completely at random between 0 and 1 with all equally sized sets of values being equally likely. This is a standard uniform distribution which has the CDF,

$$F_X(x) = x$$

with support over $[0, 1]$.

What is the probability that the number is between 0.25 and 0.5?

$$F_X(.5) - F_X(.25) = .25$$

The Core PMF/PDF Difference

The **probability mass function** provides the probability of a set of outcomes by **summing** over the probability mass function evaluated at each of those outcomes.

The **probability density function** for continuous variables provides the probability of a set of outcomes by **integrating** over a range of values.

This means (perhaps counterintuitively) that a probability density function:

- can return a value greater than 1
- assigns the probability of any exact value is zero.

Let's explain!

A Numerical Example

Let's suppose we have someone throwing darts and we measure how far they are from the center of the wall in inches. In this case, perhaps the darts will be distributed with the following PDF.

A Numerical Example

How would we calculate the probability that a dart lands within 6 inches of the center of the wall?

$$\begin{aligned}P(X \in (-6, 6)) &= \int_{-6}^6 f_X(x) dx \\&= F_X(6) - F_X(-6) \\&= P(X < 6) - P(X < -6) \\&= 0.683\end{aligned}$$

One inch?

$$P(X \in (-1, 1)) = 0.0664135$$

1/100th of an inch?

$$P(X \in (-.01, .01)) = 0.0006649037$$

A perfect bullseye?

$$P(X = 0) = 0$$

The probability that a continuous variable takes on a discrete value is **0**!
Why?

Because the **width** of the range we are calculating is **zero**, the area is zero.

The Practical Upshot

- The **cumulative distribution function** (CDF) has the same interpretation between discrete and continuous.
- The **probability mass function** (PMF) is for discrete variables and returns a probability.
- The **probability density function** (PDF) is for continuous variables and provides a probability when integrated over a subset of the support.
- Reconciling the continuous/discrete divide is the purview of **measure theory** which is a layer deeper than we are going to go in this class.
- As with discrete random variables there are common families of distributions.

Characterizing Distributions

Distributions have all kinds of wonky shapes. How do we characterize what they look like?

Expectation

The expected value of a random variable X is denoted by $E[X]$ and is a measure of **central tendency** of X . Roughly speaking, an expected value is like a weighted average of all of the **values** weighted by **probability of occurrence**.

The expected value of a *discrete* random variable X is defined as

$$E[X] = \sum_{\text{all } x} x \cdot p_X(x).$$

The expected value of a *continuous* random variable X is defined as

$$E[X] = \int_{-\infty}^{\infty} x \cdot f_X(x) dx.$$

What did we expect for Obama's NH position?

Candidates:

• Joe Biden	4/26	× 1
• Hillary Clinton	4/26	× 2
• Chris Dodd	2/26	× 3
• John Edwards	1/26	× 4
• Mike Gravel	1/26	× 5
• Dennis Kucinich	1/26	× 6
• Barack Obama	10/26	× 7
• Bill Richardson	3/26	× 8
		4.88

A,B,C,D,E,F,G,H,I,J,K,L,M,N,O,P,Q,R,S,T,U,V,W,X,Y,Z

Interpreting Discrete Expected Value

The expected value for a discrete random variable is the balance point of the mass function.

Interpreting Continuous Expected Value

The expected value for a continuous random variable is the balance point of the density function.

Why the Expected Value (Balance Point)?

- It is the probabilistic equivalent of the sample average (mean).
- It is a reasonable measure for the “center” of the data.
- We have some intuition about balance points.
- It has some useful and convenient properties.

Population Mean as an Expected Value

Let $x_1, \dots, x_N$ be our population. Then the population mean is the following

$$\bar{x} = \frac{1}{N} \sum_{i=1}^N x_i$$

This can be re-written in the following form:

$$\bar{x} = \sum_{i=1}^N \left\{ \frac{1}{N} x_i \right\}$$

Note how this resembles the definition of discrete expected value. If all values distinct (i.e. $x_i \neq x_j$ for all $i \neq j$).

$$\bar{x} = \sum_{\text{all } x_i} x_i f_X(x_i), \text{ where } f_X(x_i) = \frac{1}{N}$$

Three properties of expectation:

- Additivity
- Homogeneity
- LOTUS

Property 1 of Expected Value: Additivity

Expectations of sums are sums of expectations.

Suppose we have k random variables $X_1, \dots, X_k$. If $E[X_i]$ exists for all $i = 1, \dots, k$, then

$$E \left[\sum_{i=1}^k X_i \right] = E[X_1] + \dots + E[X_k]$$

Property 2 of Expected Value: Homogeneity

- The expected value of a constant is the constant.
- The expectation of a constant times a random variable is the constant times the expectation of the random variable.

Suppose a and b are constants and X is a random variable. Then

$$E[b] = b$$

$$E[aX] = aE[X]$$

$$E[aX + b] = aE[X] + b$$

Together properties 1 and 2 are **linearity** (and this is sometimes presented as Linearity of Expectations).

Property 3 of Expected Value: LOTUS

Law of the Unconscious Statistician: If $g(X)$ is a function of a discrete random variable, then

$$E[g(X)] = \sum_x g(x)f_X(x),$$

essentially the expected value of the transformation of the random variable is just the weighted average of the transformed outcomes.

This means we can calculate the expected value of $g(X)$ **without** explicitly knowing the distribution of $g(X)$.

Why the name LOTUS? “because this can be done very easily and mechanically, perhaps in a state of unconsciousness.” (Blitzstein and Hwang, Sec 4.5)

Summary of Expected Value Properties

The three properties:

- 1) Additivity: expectation of sums are sums of expectations

$$E[X + Y] = E[X] + E[Y]$$

- 2) Homogeneity: expected value of a constant is the constant

$$E[aX + b] = aE[X] + b$$

- 3) LOTUS: Law of the Unconscious Statistician

$$E[g(X)] = \sum_x g(x)f_X(x)$$

Two common misunderstandings about expected value

- $E[g(X)] = g(E[X])$ only if $g(\cdot)$ is a linear function
- $E[XY] = E[X]E[Y]$ only if X and Y are independent

Example: Assessing Racial Prejudice

- We often want to ask **sensitive** questions which a survey respondent is unlikely to honestly answer
- A **list experiment** asks respondents how many items on a list they agree with
 - ▶ for example, what proportion of people would be upset by a black family moving in next door to them (Kuklinski et al 1997).
 - ▶ randomly split survey into two halves
 - ▶ first half ask how many of the following items upset you:
 1. the federal government increasing the tax on gasoline.
 2. professional athletes getting million-dollar salaries.
 3. large corporations polluting the environment.
 - ▶ second half, add a fourth item
 4. a black family moving in next door
 - ▶ use the answers to infer the proportion upset by the fourth item.
- We can use random variables!

Identifying the Percent Angry

Let's make this mathematical with **random variables**. This is the first step in defining an estimator and assessing its performance (more next week!).

Assume that $Y = X + A$, where for a randomly sampled respondent,

- Y = the number of angering items on **full** list.
- X = the number of angering items on **baseline** list.
- $A = 1$ if angered by a black family moving in next door.
- $A = 0$ if not angered by a black family moving in next door.

$$\begin{aligned}E[Y] &= E[X + A] \\ &= E[X] + E[A] \\ E[Y] - E[X] &= E[A]\end{aligned}$$

So if we know $E[Y]$ and $E[X]$ we can get the expected proportion angered by our item without knowing the **individual status** of anyone!

Racial Prejudice Example (Kuklinski et al, 1997)

X = # of angering items on the **baseline** list for Southerners:

x	0	1	2	3
$p_X(x)$	?	?	?	?
$\hat{p}_X(x)$	0.02	0.27	0.43	0.28
$\hat{F}_X(x)$	0.02	0.29	0.72	1.00

Y = # of angering items on the **treatment** list for Southerners:

y	0	1	2	3	4
$p_Y(y)$	?	?	?	?	?
$\hat{p}_Y(y)$	0.02	0.20	0.40	0.28	0.10
$\hat{F}_Y(y)$	0.02	0.22	0.62	0.90	1.00

Racial Prejudice Example

$X = \#$ of angering items on the **baseline** list for Southerners:

x	0	1	2	3	Sum
$\hat{p}_X(x)$	0.02	0.27	0.43	0.28	1.00
$x\hat{p}_X(x)$	0.00	0.27	0.86	0.84	1.97

$Y = \#$ of angering items on the **treatment** list for Southerners:

y	0	1	2	3	4	Sum
$\hat{p}_Y(y)$	0.03	0.20	0.40	0.28	0.10	1.00
$y\hat{p}_Y(y)$	0.00	0.20	0.80	0.84	0.40	2.24

$$\widehat{E[A]} = 2.24 - 1.97 = 0.27$$

When to Worry about Sensitivity Bias: A Social Reference Theory and Evidence from 30 Years of List Experiments

GRAEME BLAIR *University of California, Los Angeles*

ALEXANDER COPPOCK *Yale University*

MARGARET MOOR *Yale University*

*E*liciting honest answers to sensitive questions is frustrated if subjects withhold the truth for fear that others will judge or punish them. The resulting bias is commonly referred to as social desirability bias, a subset of what we label sensitivity bias. We make three contributions. First, we propose a social reference theory of sensitivity bias to structure expectations about survey responses on sensitive topics. Second, we explore the bias-variance trade-off inherent in the choice between direct and indirect measurement technologies. Third, to estimate the extent of sensitivity bias, we meta-analyze the set of published and unpublished list experiments (a.k.a., the item count technique) conducted to date and compare the results with direct questions. We find that sensitivity biases are typically smaller than 10 percentage points and in some domains are approximately zero.

Variance: A Measure of Dispersion

Expectation told us about the central tendency of a random variable, but what about **dispersion**?

The expected value of a function $g()$ of the random variable X is denoted by $E[g(X)]$ and measures the central tendency of $g(X)$.

The variance is a special case of this, and the variance of a random variable X (a measure of its dispersion) is given by

$$\begin{aligned} V[X] &= E[(X - E[X])^2] \\ &= E[X^2] - E[X]^2 \end{aligned}$$

It is the expectation of the squared distances from the mean.

For a **discrete** random variable X

$$V[X] = \sum_{\text{all } x} (x - E[X])^2 p_X(x)$$

For a **continuous** random variable X

$$V[X] = \int_{-\infty}^{\infty} (x - E[X])^2 f_X(x) dx$$

Variance Measures the Spread of a Distribution

Why the Variance?

- It is a reasonable measure for the “spread” of a distribution.
- The Normal distribution—more later this week—is completely determined by its expected value (location) and variance (spread).
- The square root of the variance is the standard deviation.
- The variance and standard deviation have some useful properties.

Property 1 of Variance: Behavior with Constants

Suppose a and b are constants and X is a random variable. Then

- The variance of a constant is zero.
- The variance of a constant times a random variable is the constant squared times the variance of the random variable.

$$V[b] = 0$$

$$V[aX] = a^2 V[X]$$

$$V[aX + b] = a^2 V[X] + 0$$

Property 2 of Variance: Additivity for Independent Random Variables

Variances of sums of **independent** RVs are sums of variances.

Suppose we have k independent random variables $X_1, \dots, X_k$. If $V[X_i]$ exists for all $i = 1, \dots, k$, then

$$V \left[\sum_{i=1}^k X_i \right] = V[X_1] + \dots + V[X_k]$$

NB: Technically independence is sufficient but not necessary.

What was the variance of Obama's NH position?

Candidates:

• Joe Biden	4/26	$\times (1 - 4.88)^2$
• Hillary Clinton	4/26	$\times (2 - 4.88)^2$
• Chris Dodd	2/26	$\times (3 - 4.88)^2$
• John Edwards	1/26	$\times (4 - 4.88)^2$
• Mike Gravel	1/26	$\times (5 - 4.88)^2$
• Dennis Kucinich	1/26	$\times (6 - 4.88)^2$
• Barack Obama	10/26	$\times (7 - 4.88)^2$
• Bill Richardson	+ 3/26	$\times (8 - 4.88)^2$
		6.79

A,B,C,D,E,F,G,H,I,J,K,L,M,N,O,P,Q,R,S,T,U,V,W,X,Y,Z

Does variance matter for fairness?

One Step Deeper: Moments

Definition

Suppose X is a random variable with pdf f_X . Define,

$$E[X^n] = \int_{-\infty}^{\infty} x^n f_X(x) dx$$

We will call X^n the n^{th} moment of X

- $V(X) = \text{Second Moment} - \text{First Moment}^2$
- We are assuming that the integral converges.
- Another way to characterize distributions is with their moment-generating function.

Expected Value as Mean Squared Error Minimizer

Now we can return to the question of **why expectation?** and offer one technical answer.

Suppose we want to pick a single number (c) that **summarizes** a random variable X . What we mean by **summarizes** determines the best choice of c .

Generally speaking we want a summary that is in the “**center**” of the data, i.e. that is as close as possible to all possible datapoints. Again though, the choice turns on what we mean by **close**.

Two notions of closeness:

- Mean Squared Error: $E[(X - c)^2]$

This leads to choosing the mean of X .

- Mean Absolute Error: $E[|X - c|]$

This leads to choosing the median of X .

Let's prove the first result (see Blitzstein and Hwang 2014 Theorem 6.1.4 on pg 245 for this proof and the proof on mean absolute error).

Proof of Mean as Mean Squared Error Minimizer

Let X be a random variable and $E[X] = \mu$. We want to show that the value of c that minimizes the mean squared error $E[(X - c)^2]$ is the mean, μ (Blitzstein and Hwang Theorem 6.1.4).

We will prove the following identity below:

$$E[(X - c)^2] = V[X] + (\mu - c)^2 \quad (1)$$

We choose c to minimize this term. The choice cannot affect $V[X]$. Setting $c = \mu$ sets $(\mu - c)^2 = 0$ and any other choice makes $(\mu - c)^2 > 0$. Therefore (assuming the identity holds), $c = \mu$ minimizes Eq 1.

Now to prove the identity:

$$V[X] = V[X - c] \quad (\text{Prop 1 of Variance})$$

$$= E[(X - c)^2] - (E[X - c])^2 \quad (\text{Defn of Variance})$$

$$= E[(X - c)^2] - (\mu - c)^2 \quad (\text{Linearity of Exp})$$

$$V[X] + (\mu - c)^2 = E[(X - c)^2]$$

We Covered...

- Definition of a random variable.
- Discrete and continuous distributions
- Expectation and variance (definition, properties etc.)

Next time: Joint and Conditional Distributions (and their properties!)

The determination of the average man is not merely a matter of speculative curiosity; it may be of the most important service to the science of man and the social system. It ought necessarily to precede every other inquiry into social physics, since it is, as it were, the basis. The average man, indeed, is in a nation what the centre of gravity is in a body; it is by having that central point in view that we arrive at the apprehension of all the phenomena of equilibrium and motion

The Military Takes to the Idea

The Problem with Averages

THE EDGE **HEALTH**

Stacking Up

How does your physique stack up against the average American? We did a weight, height, and fitness analysis of 100,000 men only to find some surprising—and just wild—stats.

69%

Percent of men who consider themselves "physically fit"

13%

Percentage who actually are fit

\$874

Average spent on vitamins each year

45%

Percentage of men who said that fitness is a more important thing than clothes

52

Hours per week of men's reading habit

2.87

Hours per week of men's reading habit

1.1 lbs.

Average of fat gained each year

1

Average number of full sets

77 yrs.

Average life expectancy

23

Average age of men who are "fit"

12:17

Average time to read a book

1

Percent of men who are "fit"

Size Yourself Up

Statistic	25	35	45	55	65
Weight (lbs.)	155	170	185	200	215
Height (in.)	5'7	5'8	5'9	5'10	5'11
Push-ups (in 1 min.)	15	20	25	30	35
Beach Press (in 1 min.)	20	25	30	35	40

5'9.2"

The average of all men's heights

40"

Size of the average guy's chest (inches)
This is also the average chest size of the 100,000 men who are "fit"

17.6%

Average body fat

13"

Size of the average guy's bicep (inches)

34"

Average waist (inches)

5.08

The average set is length is 5 inches, according to The Journal of Strength & Conditioning Research. The average set is length is 5 inches, according to The Journal of Strength & Conditioning Research. The average set is length is 5 inches, according to The Journal of Strength & Conditioning Research.

Sex Stats

The average man's sex life is 2.5 times longer than the average woman's sex life. The average man's sex life is 2.5 times longer than the average woman's sex life. The average man's sex life is 2.5 times longer than the average woman's sex life.

The Face of the Average Man

- 4 Expectation as a Measure of Central Tendency
- 5 Variance as a Measure of Dispersion
- 6 Fun With Averages
- 7 Joint and Conditional Distributions**
 - First Visual Example
 - Discrete Random Variable
 - Continuous Random Variable

Joint Distributions

- We've talked about joint probabilities of events—what was the probability of A and B occurring: $P(A \cap B)$
- We also talked about the **conditional probability** of A given that B occurred.
- We also need to think about more than one random variable at the same time.
- The **joint distribution** of two (or more) variables describes the pairs of observations that we are more or less likely to see.
- The **conditional distribution** describes one random variable given knowledge of another.
- We will start with a visual preview, then step back to go through the math more concretely.

Understanding Joint Distributions Mathematically

- Consider two random variables now, X and Y , each on the real line, $\mathbb{R}$.
- The pair form a two-dimensional space, or $\mathbb{R} \times \mathbb{R}$
- One realization of the random variable is a point in that space

Example: Racial Prejudice

- Recall the list experiment about racial prejudice. Suppose we define $X = 0$ (Non-southern), 1 (Southern) and $Y =$ “number of angering items” for a randomly selected respondent receiving the treatment list.
- Furthermore, we define the probability that this respondent will have the values $X = x$ and $Y = y$ to be $p_{Y,X}(y, x) = \pi_{yx}$

$$X = \begin{array}{c} \text{N} \\ \text{W} \downarrow \text{E} \\ \text{S} \end{array}, \begin{array}{c} \text{N} \\ \text{W} \rightarrow \text{E} \\ \text{S} \end{array}$$

$$Y = \begin{array}{cc} \text{😊😊} \\ \text{😊😊} \end{array}, \begin{array}{cc} \text{😡😊} \\ \text{😊😊} \end{array}, \begin{array}{cc} \text{😡😡} \\ \text{😊😊} \end{array}, \begin{array}{cc} \text{😡😡} \\ \text{😡😊} \end{array}, \begin{array}{cc} \text{😡😡} \\ \text{😡😡} \end{array}$$

$$f(\begin{array}{cc} \bullet\bullet \\ \bullet\bullet \end{array}, \begin{array}{c} \text{N} \\ \text{W} \downarrow \text{E} \\ \text{S} \end{array}) = \pi_{\begin{array}{cc} \bullet\bullet \\ \bullet\bullet \end{array} \begin{array}{c} \text{N} \\ \text{W} \downarrow \text{E} \\ \text{S} \end{array}}$$

Example Joint Distribution: Binary X, Discrete Y

Although we cannot observe the responses for the entire population, we can imagine what they might look like as a joint distribution.

$f(\text{☼}, \text{⌚})$	$\mathbf{x} = \text{⌚}$		$f(\text{☼})$
$\mathbf{y}$			
	$\pi_{\text{☼}, \text{⌚}}$ 	$\pi_{\text{☼}, \text{⌚}}$ 	$\pi_{\text{☼}, \text{⌚}}$  + $\pi_{\text{☼}, \text{⌚}}$ 
	$\pi_{\text{☼}, \text{⌚}}$ 	$\pi_{\text{☼}, \text{⌚}}$ 	$\pi_{\text{☼}, \text{⌚}}$  + $\pi_{\text{☼}, \text{⌚}}$ 
	$\pi_{\text{☼}, \text{⌚}}$ 	$\pi_{\text{☼}, \text{⌚}}$ 	$\pi_{\text{☼}, \text{⌚}}$  + $\pi_{\text{☼}, \text{⌚}}$ 
	$\pi_{\text{☼}, \text{⌚}}$ 	$\pi_{\text{☼}, \text{⌚}}$ 	$\pi_{\text{☼}, \text{⌚}}$  + $\pi_{\text{☼}, \text{⌚}}$ 
	$\pi_{\text{☼}, \text{⌚}}$ 	$\pi_{\text{☼}, \text{⌚}}$ 	$\pi_{\text{☼}, \text{⌚}}$  + $\pi_{\text{☼}, \text{⌚}}$ 
$f(\text{⌚})$	$\sum_{\text{☼}} \pi_{\text{☼}, \text{⌚}}$ 	$\sum_{\text{☼}} \pi_{\text{☼}, \text{⌚}}$ 	

Discrete Conditional Distribution

$$f(\text{four dots} | \text{clock}) = \frac{f(\text{four dots}, \text{clock})}{f(\text{clock})}$$

$y = \text{four dots}$

$x = \text{clock}$

$$\frac{\pi_{\text{four dots}, \text{clock}}}{\sum_{\text{four dots}} \pi_{\text{four dots}, \text{clock}}}$$

$$\frac{\pi_{\text{four dots}, \text{clock}}}{\sum_{\text{four dots}} \pi_{\text{four dots}, \text{clock}}}$$

$$\frac{\pi_{\text{four dots}, \text{clock}}}{\sum_{\text{four dots}} \pi_{\text{four dots}, \text{clock}}}$$

$$\frac{\pi_{\text{four dots}, \text{clock}}}{\sum_{\text{four dots}} \pi_{\text{four dots}, \text{clock}}}$$

$$\frac{\pi_{\text{four dots}, \text{clock}}}{\sum_{\text{four dots}} \pi_{\text{four dots}, \text{clock}}}$$

$$\frac{\pi_{\text{four dots}, \text{clock}}}{\sum_{\text{four dots}} \pi_{\text{four dots}, \text{clock}}}$$

$$\frac{\pi_{\text{four dots}, \text{clock}}}{\sum_{\text{four dots}} \pi_{\text{four dots}, \text{clock}}}$$

$$\frac{\pi_{\text{four dots}, \text{clock}}}{\sum_{\text{four dots}} \pi_{\text{four dots}, \text{clock}}}$$

$$\frac{\pi_{\text{four dots}, \text{clock}}}{\sum_{\text{four dots}} \pi_{\text{four dots}, \text{clock}}}$$

$$\frac{\pi_{\text{four dots}, \text{clock}}}{\sum_{\text{four dots}} \pi_{\text{four dots}, \text{clock}}}$$

Joint Probability Mass Function

Definition

For two discrete random variables X and Y the **joint** Probability Mass Function (PMF) $P_{X,Y}(x,y)$ gives the probability that $X = x$ and $Y = y$ for all x and y :

$$p_{X,Y}(x,y) = P(X = x \text{ and } Y = y)$$

Restrictions:

- $p_{X,Y}(x,y) \geq 0$ and $\sum_x \sum_y p_{X,Y}(x,y) = 1$.

Joint Probability Mass Function

Definition

For two discrete random variables X and Y the **joint** Probability Mass Function (PMF) $p_{X,Y}(x,y)$ gives the probability that $X = x$ and $Y = y$ for all x and y :

$$p_{X,Y}(x,y) = P(X = x \text{ and } Y = y)$$

Should the U.S. allow more immigrants to come and live here?

		X: Education			
		less HS	HS	College	BA
Y: Support	oppose	0.07	0.22	0.18	0.15
	neutral	0.02	0.06	0.05	0.05
	favor	0.01	0.03	0.04	0.11

With discrete random variables this is very similar to thinking about a cross-tab, with frequencies/ probabilities in the cells instead of raw numbers.

Joint Probability Mass Function

From Joint to Marginal PMF

Given the **joint** PMF $p_{X,Y}(x,y)$ can we recover the **marginal** PMF $p_Y(y)$ (distribution over a single variable)?

		X: Education				
		less HS	HS	College	BA	$p_Y(y)$
Y: Support	oppose	0.07	0.21	0.17	0.14	0.62
	neutral	0.02	0.06	0.05	0.05	0.19
	favor	0.01	0.03	0.04	0.10	0.19

To obtain $p_Y(y)$ we **marginalize** the joint probability function $p_{X,Y}(x,y)$ over X :

$$p_Y(y) = \sum_x p_{X,Y}(x,y) = \sum_x P(X = x, Y = y)$$

Joint and Marginal Probability Mass Functions

Why Does Marginalization Work?

Begin with **discrete** case. Consider jointly distributed discrete random variables, X and Y . We'll suppose they have joint pmf,

$$P(X = x, Y = y) = p_{X,Y}(x, y)$$

Suppose that the distribution allocates its mass at $x_1, x_2, \dots, x_M$ and $y_1, y_2, \dots, y_N$.

Define the conditional mass function $P(X = x|Y = y)$ as,

$$\begin{aligned} P(X = x|Y = y) &\equiv p_{X|Y}(x|y) \\ &= p_{X,Y}(x, y)/p_Y(y) \end{aligned}$$

Then it follows that:

$$p_{X,Y}(x, y) = p_{X|Y}(x|y)p_Y(y)$$

Marginalizing **over** y to get $p_X(x)$ is then,

$$p_X(x_j) = \sum_{i=1}^N p_{X|Y}(x_j|y_i)p_Y(y_i)$$

A Table

	Y = 0	Y = 1	
X = 0	p(0,0)	p(0, 1)	p _X (0)
X = 1	p(1,0)	p(1,1)	p _X (1)
	p _Y (0)	p _Y (1)	
	Y = 0	Y = 1	
X = 0	0.01	0.05	?
X = 1	0.25	0.69	?
	0.26	0.74	

$$\begin{aligned}
 p_X(0) &= P(X=0|Y=0)P(Y=0) + P(X=0|Y=1)P(Y=1) \\
 &= \frac{0.01}{0.26} \times 0.26 + \frac{0.05}{0.74} \times 0.74 \\
 &= 0.06
 \end{aligned}$$

$$\begin{aligned}
 p_X(1) &= P(X=1|Y=0)P(Y=0) + P(X=1|Y=1)P(Y=1) \\
 &= \frac{0.25}{0.26} \times 0.26 + \frac{0.69}{0.74} \times 0.74 \\
 &= 0.94
 \end{aligned}$$

Conditional PMF

Definition

The **conditional** PMF of Y given X , $p_{Y|X}(y|x)$, is the PMF of Y when X is known to be at a particular value $X = x$:

$$p_{Y|X}(y|x) = \frac{P(X = x \text{ and } Y = y)}{P(X = x)} = \frac{p_{X,Y}(x, y)}{p_X(x)}$$

Key relationships:

- $p_{X,Y}(x, y) = p_{Y|X}(y|x)p_X(x)$ (multiplicative rule)
- $p_{Y|X}(y|x) = p_{X|Y}(x|y)p_Y(y)/p_X(x)$ (Bayes' rule)

Conditional PMFs are just like ordinary PMFs, but refer to a universe where the “conditioning event” ($X = x$) is known to have occurred.

Conditional distributions are key in statistical modeling because they inform us how the distribution of Y varies across different levels of X .

From Joint to Conditional: $p_{Y|X}(y|x) = \frac{p_{X,Y}(x,y)}{p_X(x)}$

Table: Joint PMF $p_{X,Y}(x,y)$ and Marginal PMFs $p_X(x), p_Y(y)$

Joint Probability Density Function

Definition

For two **continuous** random variables X and Y the **joint** PDF $f_{X,Y}(x,y)$ gives the density height where $X = x$ and $Y = y$ for all x and y .

The multiplicative rule:

$$f_{X,Y}(x,y) = f_{Y|X}(y|x)f_X(x)$$

where

- $f_{Y|X}(y|x)$: **Conditional** PDF of Y given $X = x$
- $f_X(x)$: **Marginal** PDF of X

Restrictions:

- $\int_x \int_y f_{X,Y}(x,y) dy dx = 1$

3D Plot of a Joint Probability Density Function

Bivariate Normal Distribution: $z = f_{X,Y}(x, y)$

Contour Plot of a Joint Probability Density Function

From Joint to Marginal PDF

How can we obtain $f_Y(y)$ from $f_{X,Y}(x,y)$?

We marginalize the joint probability function $f_{X,Y}(x,y)$ over X :

$$f_Y(y) = \int_{-\infty}^{\infty} f_{X,Y}(x,y) dx$$

Joint PDF $f(x,y)$

Marginal PDF $f(y)$

- 7 Joint and Conditional Distributions
- 8 Characterizing Conditional Distributions**
 - Conditional Expectation
 - Conditional Variance

Remember this?

Conditioning on X

- A common goal in statistical modeling is to characterize the conditional distribution of the outcome variable $f_{Y|X}(y|x)$ across different levels of $X = x$.
- Typically, we summarize the conditional distributions with a few parameters such as the **conditional mean** of $E[Y|X = x]$ and the **conditional variance** $V[Y|X = x]$
- Moreover, we are often interested in estimating $E[Y|X]$, i.e. the **conditional expectation function** that describes how the conditional mean of Y varies across all possible values of X .

Conditional Expectation

Definition (Conditional Expectation (Discrete))

Let Y and X be discrete random variables. The conditional expectation of Y given $X = x$ is defined as:

$$E[Y|X = x] = \sum_y y P(Y = y|X = x) = \sum_y y p_{Y|X}(y|x)$$

Definition (Conditional Expectation (Continuous))

Let Y and X be continuous random variables. The conditional expectation of Y given $X = x$ is given by:

$$E[Y|X = x] = \int_{-\infty}^{\infty} y f_{Y|X}(y|x) dy$$

Joint and Conditional Probability Mass Functions

Conditional PMF $P_{Y|X}(y|x)$

Conditional Expectation $E[Y|X = 1]$

Conditional Expectation Function $E[Y|X]$

Law of Iterated Expectations

Theorem (Law of Iterated Expectations/Adam's Law)

For two random variables X and Y ,

$$E[Y] = E[E[Y|X]] = \begin{cases} \sum E[Y|X=x] \cdot p_X(x) & (\text{discrete } X) \\ \int_{-\infty}^{\infty} E[Y|X=x] \cdot f_X(x) dx & (\text{continuous } X) \end{cases}$$

Note that the outer expectation is taken with respect to the distribution of X .

Example: Y (support) and $X \in \{1, 0\}$ (AfAm). Then, the LIE tells us:

$$\underbrace{E[Y]}_{\text{Average Support}} = \underbrace{E[E[Y|X]]}_{\text{Average Support|AfAm}^c} = \underbrace{E[Y|X=1]}_{\text{Average Support|AfAm}^c} \cdot \underbrace{p_X(1)}_{P(\text{AfAm}^c)} + \underbrace{E[Y|X=0]}_{\text{Average Support|AfAm}} \cdot \underbrace{p_X(0)}_{P(\text{AfAm})}$$

Properties of Conditional Expectation

Conditional expectations have some convenient properties

- ① $E[c(X)|X] = c(X)$ for any function $c(X)$.
 - ▶ Basically, any function of X is a constant with regard to the conditional expectation. If we know X , then we also know X^2 , for instance.
- ② $E[(Y - E[Y|X])^2] \leq E[(Y - g(X))^2]$
(given $E[Y^2] < \infty$ and $E[g(X)^2] < \infty$ for some function g)
 - ▶ This says that the conditional expectation is the function of X that **minimizes the squared prediction error** for Y across any possible function of X .
 - ▶ This is analogous to the result we saw about the mean.

Conditional Variance

Conditional expectation gives us information about the **central tendency** of a random variable given another random variable.

We also want to know the **conditional variance** to understand our uncertainty about the conditional distribution.

Remember, the conditional distribution of $Y|X$ is basically like any other probability distribution, so we are going to want to summarize the **center and spread**.

Conditional Variance

Definition

The **conditional variance** of Y given $X = x$ is defined as:

$$V[Y|X = x] = \begin{cases} \sum_{\text{all } y} (y - E[Y|X = x])^2 P_{Y|X}(y|x) & \text{(discrete } Y) \\ \int_{-\infty}^{\infty} (y - E[Y|X = x])^2 f_{Y|X}(y|x) dy & \text{(continuous } Y) \end{cases}$$

A useful related result is the **law of total variance** (Eve's Law):

$$\underbrace{V[Y]}_{\text{Total variance}} = \underbrace{E[V[Y|X]]}_{\text{Average of Group Variances}} + \underbrace{V[E[Y|X]]}_{\text{Variance in Group Averages}}$$

Example: Y (support) and $X \in \{1, 0\}$ (group). The LTV says that the total variance in support can be decomposed into two parts:

- 1 On average, how much support varies within groups (**within variance**)
- 2 How much average support varies between groups (**between variance**)

Conditional Variance Function $V[Y|X]$

Subtleties

- It is important to distinguish between what is **random/stochastic** and what is **constant**. However, this can be tricky at first.
- If X is a random variable, generally a function of X ($g(X)$) is also a random variable.
- $E[X]$ is a constant though (we sometimes refer to $E[\cdot]$ as an operator to make clear it doesn't behave the same as $g(\cdot)$).
- Why? There is no longer anything **stochastic** in $E[X]$. Take the discrete case: $E[X] = \sum_x xp_X(x)$. Note that this is entirely in terms of realized values.
- By contrast, $E[X|Y]$ is random.
- $E[X|Y]$ is a function into which one can plug a value of $Y = y$ and get the expectation of X conditional on that value. Thus the randomness 'comes from' Y .

Let's look at this in pictures.

- 1 Definition of Random Variables
- 2 Discrete Distributions
- 3 Continuous Distribution
- 4 Expectation as a Measure of Central Tendency
- 5 Variance as a Measure of Dispersion
- 6 Fun With Averages
- 7 Joint and Conditional Distributions
- 8 Characterizing Conditional Distributions
- 9 Independence and Covariance

Independence

Definition (Independence of Random Variables)

Two random variables Y and X are independent if

$$f_{X,Y}(x,y) = f_X(x)f_Y(y)$$

for all x and y . We write this as $Y \perp\!\!\!\perp X$.

Independence implies

$$f_{Y|X}(y|x) = f_Y(y)$$

and thus

$$E[Y|X = x] = E[Y]$$

Is $Y \perp\!\!\!\perp X$?

Expected Values with Independent Random Variables

If random variables X and Y are independent, then

$$E[XY] = E[X]E[Y]$$

Proof: For discrete X and Y ,

$$\begin{aligned} E[XY] &= \sum_{\text{all } x} \sum_{\text{all } y} x y p_{X,Y}(x, y) \\ &= \sum_{\text{all } x} \sum_{\text{all } y} x y p_X(x) p_Y(y) \\ &= \sum_{\text{all } x} x p_X(x) \sum_{\text{all } y} y p_Y(y) \\ &= E[X]E[Y] \end{aligned}$$

We can prove the continuous case by following the same steps, with $\sum$ replaced by $\int$.

Covariance

Definition

The **covariance** of X and Y is defined as:

$$\begin{aligned}\text{Cov}[X, Y] &= E[(X - E[X])(Y - E[Y])] \\ &= E[XY] - E[X]E[Y]\end{aligned}$$

- Covariance measures the **linear association** between two random variables .
- If $\text{Cov}[X, Y] > 0$, observing an X value greater than $E[X]$ makes it more likely to also observe a Y value greater than $E[Y]$, and vice versa.

- Points in upper right and lower left quadrants (relative to the means) add to the covariance.
- Points in the upper left and lower right quadrants subtract from the covariance.

Covariance and Independence

Does $X \perp\!\!\!\perp Y$ imply $\text{Cov}[X, Y] = 0$? Yes!

Proof:

$$\begin{aligned}\text{Cov}[X, Y] &= E[XY] - E[X]E[Y] \\ &= E[X]E[Y] - E[X]E[Y] \quad (\text{independence}) \\ &= 0.\end{aligned}$$

Does $\text{Cov}[X, Y] = 0$ imply $X \perp\!\!\!\perp Y$? No!

Counterexample: Suppose $X \in \{-1, 0, 1\}$ with $p_X(x) = 1/3$ and $Y = X^2$.

Is $X \perp\!\!\!\perp Y$? No, because $p_{Y|X}(y | x) \neq p_Y(y)$

(Learning about X gives meaningful information about Y .)

What is $\text{Cov}[X, Y]$?

$$\begin{aligned}\text{Cov}[X, Y] &= E[XX^2] - E[X]E[X^2] = E[X^3] - E[X]E[X^2] \\ &= E[X] - E[X]E[X^2] = 0 - 0 \cdot E[X^2] = 0.\end{aligned}$$

Therefore, $X \perp\!\!\!\perp Y \implies \text{Cov}[X, Y] = 0$, but not vice versa.

Important Identities for Variances and Covariances

- ① For random variables X and Y and constants a, b and c ,

$$V[aX + bY + c] = a^2 V[X] + b^2 V[Y] + 2ab \operatorname{Cov}[X, Y]$$

- ② Important special cases:

$$V[X + Y] = V[X] + V[Y] + 2\operatorname{Cov}[X, Y]$$

$$V[X - Y] = V[X] + V[Y] - 2\operatorname{Cov}[X, Y]$$

- ③ Furthermore, if X and Y are independent,

$$V[X \pm Y] = V[X] + V[Y]$$

Proof: Plug in to the definition of variance and expand (try it yourself!)

Correlation

- $\text{Cov}[X, Y]$ depends not only on the strength of (linear) association between X and Y , but also the scale of X and Y .
- Can we have a pure measure of association that is scale-independent?

Definition (Correlation)

The **correlation** between two random variables X and Y is defined as

$$\text{Cor}[X, Y] = \frac{\text{Cov}[X, Y]}{\sqrt{V[X]V[Y]}} = \frac{\text{Cov}[X, Y]}{SD[X]SD[Y]}.$$

- $\text{Cor}[X, Y]$ is a standardized measure of linear association between X and Y .
- Always satisfies: $-1 \leq \text{Cor}[X, Y] \leq 1$.

Correlation is *Linear*

- $Cor[X, Y] = \pm 1$ iff $Y = aX + b$ where $a \neq 0$.
- Like covariance, correlation measures the **linear** association between X and Y .

Conditional Independence

Definition (Conditional Independence of Random Variables)

Random variables Y and X are conditionally independent given Z iff

$$f_{X,Y|Z}(x,y|z) = f_{Y|Z}(y|z) \cdot f_{X|Z}(x|z)$$

for all x , y , and z . This is often written as $Y \perp\!\!\!\perp X \mid Z$.

- Can also be written as

$$f_{Y|X,Z}(y \mid x, z) = f_{Y|Z}(y \mid z)$$

- Interpretation: Once we know Z , X contains no meaningful information about likely values of Y .
(Z has all the information about Y contained in X , if any.)
- $Y \perp\!\!\!\perp X \mid Z$ implies

$$E[Y|X = x, Z = z] = E[Y|Z = z].$$

Is $Y \perp\!\!\!\perp X$?

Example: X = wealth, Y = support for immigration, Z = education.

Is $Y \perp\!\!\!\perp X | Z$?

Example: X = wealth, Y = support for immigration, Z = education.

Where We've Been and Where We're Going...

- Last Week

- ▶ welcome and outline of course
- ▶ described uncertain outcomes with **probability**.

- This Week

- ▶ define **random variables**
- ▶ summarize random variables using **expectation** and **variance**
- ▶ properties of **joint** and **conditional** distributions
- ▶ famous distributions

- Next Week

- ▶ **estimating** these features from data
- ▶ estimating **uncertainty**

- Long Run

- ▶ probability $\rightarrow$ inference $\rightarrow$ regression $\rightarrow$ causal inference

- 1 Definition of Random Variables
- 2 Discrete Distributions
- 3 Continuous Distribution
- 4 Expectation as a Measure of Central Tendency
- 5 Variance as a Measure of Dispersion
- 6 Fun With Averages
- 7 Joint and Conditional Distributions
- 8 Characterizing Conditional Distributions
- 9 Independence and Covariance

Distributions

- We like random variables because they take complex real world phenomena and represent them with a common mathematical **infrastructure**.
- We can work with arbitrary pmf/pdfs but we will often work with particular **families of distributions**.
 - ▶ members of the same family have similar forms determined by parameters
 - ▶ the parameters determine the shape of the distribution
- When we can work with an existing set of distributions, it makes calculations simpler
- Examples: Bernoulli, Binomial, Gamma, Normal, Poisson, t -distribution

Bernoulli Random Variable

Definition

Suppose X is a random variable, with $X \in \{0, 1\}$ and $P(X = 1) = \pi$. Then we will say that X is **Bernoulli** random variable,

$$P(X = x) = \pi^x(1 - \pi)^{1-x}$$

for $x \in \{0, 1\}$ and $P(X = x) = 0$ otherwise.

We will (equivalently) say that

$$X \sim \text{Bernoulli}(\pi)$$

$\sim$ means equality in distribution (not values!). Often $X \sim \text{Bernoulli}(\pi)$ would be read 'X is distributed Bernoulli with parameter π '

Bernoulli Random Variable Mean and Variance

Suppose $X \sim \text{Bernoulli}(\pi)$

$$\begin{aligned} E[X] &= 1 \times P(X = 1) + 0 \times P(X = 0) \\ &= \pi + 0(1 - \pi) = \pi \end{aligned}$$

$$\text{var}(X) = E[X^2] - E[X]^2$$

$$\begin{aligned} E[X^2] &= 1^2 P(X = 1) + 0^2 P(X = 0) \\ &= \pi \end{aligned}$$

$$\begin{aligned} \text{var}(X) &= \pi - \pi^2 \\ &= \pi(1 - \pi) \end{aligned}$$

$$E[X] = \pi$$

$$\text{var}(X) = \pi(1 - \pi)$$

Importantly, we can also just look this up!

Normal/Gaussian Random Variables

Definition

Suppose X is a random variable with $X \in \mathbb{R}$ and **density**

$$f_X(x) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right)$$

Then X is a **normally** distributed random variable with parameters μ and σ^2 .

Equivalently, we'll write

$$X \sim \text{Normal}(\mu, \sigma^2)$$

Expected Value/Variance of Normal Distribution

Z is a standard normal distribution if

$$Z \sim \text{Normal}(0, 1)$$

We'll call the cumulative distribution function of Z ,

$$F_Z(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x \exp(-z^2/2) dz$$

Proposition

Scale/Location. If $Z \sim N(0, 1)$, then $X = aZ + b$ is,

$$X \sim \text{Normal}(b, a^2)$$

Intuition

Suppose $Z \sim \text{Normal}(0, 1)$.

$$Y = 2Z + 6$$

$$Y \sim \text{Normal}(6, 4)$$

Expectation and Variance

Assume we know:

$$E[Z] = 0$$

$$\text{Var}(Z) = 1$$

This implies that, for $Y \sim \text{Normal}(\mu, \sigma^2)$

$$E[Y] = E[\sigma Z + \mu]$$

$$= \sigma E[Z] + \mu$$

$$= \mu$$

$$\text{Var}(Y) = \text{Var}(\sigma Z + \mu)$$

$$= \sigma^2 \text{Var}(Z) + \text{Var}(\mu)$$

$$= \sigma^2 + 0$$

$$= \sigma^2$$

Multivariate Normal

Definition

Suppose $\mathbf{X} = (X_1, X_2, \dots, X_N)$ is a vector of random variables. If $\mathbf{X}$ has pdf

$$f_{X_1, X_2}(\mathbf{x}) = (2\pi)^{-N/2} \det(\mathbf{\Sigma})^{-1/2} \exp\left(-\frac{1}{2}(\mathbf{x} - \boldsymbol{\mu})' \mathbf{\Sigma}(\mathbf{x} - \boldsymbol{\mu})\right)$$

Then we will say $\mathbf{X}$ has a **Multivariate Normal** Distribution,

$$\mathbf{X} \sim \text{Multivariate Normal}(\boldsymbol{\mu}, \mathbf{\Sigma})$$

Multivariate Normal Distribution

Consider the (bivariate) special case where $\boldsymbol{\mu} = (0, 0)$ and

$$\boldsymbol{\Sigma} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

Then

$$\begin{aligned} f(x_1, x_2) &= (2\pi)^{-2/2} 1^{-1/2} \exp \left(-\frac{1}{2} \left((\mathbf{x} - \mathbf{0})' \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} (\mathbf{x} - \mathbf{0}) \right) \right) \\ &= \frac{1}{2\pi} \exp \left(-\frac{1}{2} (x_1^2 + x_2^2) \right) \\ &= \frac{1}{\sqrt{2\pi}} \exp \left(-\frac{x_1^2}{2} \right) \frac{1}{\sqrt{2\pi}} \exp \left(-\frac{x_2^2}{2} \right) \end{aligned}$$

$\rightsquigarrow$ product of univariate standard normally distributed random variables

Properties of the Multivariate Normal Distribution

Suppose $\mathbf{X} = (X_1, X_2, \dots, X_N)$

$$\begin{aligned} E[\mathbf{X}] &= \boldsymbol{\mu} \\ \text{cov}(\mathbf{X}) &= \boldsymbol{\Sigma} \end{aligned}$$

So that,

$$\boldsymbol{\Sigma} = \begin{pmatrix} \text{var}(X_1) & \text{cov}(X_1, X_2) & \dots & \text{cov}(X_1, X_N) \\ \text{cov}(X_2, X_1) & \text{var}(X_2) & \dots & \text{cov}(X_2, X_N) \\ \vdots & \vdots & \ddots & \vdots \\ \text{cov}(X_N, X_1) & \text{cov}(X_N, X_2) & \dots & \text{var}(X_N) \end{pmatrix}$$

Summary

- Random variables and probability distributions provide useful **models** of the world
- We can characterize distributions in terms of their **expectation** (location) and **variance** (spread).
- **Joint** and **conditional** distributions capture the relationship between random variables.
- There is a common set of famous distributions such as the **Normal** distribution.
